ANNEX I

SUMMARY OF PRODUCT CHARACTERISTICS
This medicinal product is subject to additional monitoring. This will allow quick identification of new safety information. Healthcare professionals are asked to report any suspected adverse reactions. See section 4.8 for how to report adverse reactions.

1. **NAME OF THE MEDICINAL PRODUCT**

Lutathera 370 MBq/mL solution for infusion

2. **QUALITATIVE AND QUANTITATIVE COMPOSITION**

One mL of solution contains 370 MBq of lutetium ($^{177}$Lu) oxodotreotide at the date and time of calibration.

The total amount of radioactivity per single dose vial is 7,400 MBq at the date and time of infusion. Given the fixed volumetric activity of 370 MBq/mL at the date and time of calibration, the volume of the solution is adjusted between 20.5 mL and 25.0 mL in order to provide the required amount of radioactivity at the date and time of infusion.

Lutetium ($^{177}$Lu) has a half-life of 6.647 days. Lutetium ($^{177}$Lu) decays by β− emission to stable Hafnium ($^{177}$Hf) with the most abundant β− (79.3%) having a maximum energy of 0.497 MeV. The average beta energy is approximately 0.13 MeV. Low gamma energy is also emitted, for instance at 113 keV (6.2%) and 208 keV (11%).

**Excipient with known effect**
Each mL of solution contains 0.14 mmol (3.2 mg) of sodium.

For the full list of excipients, see section 6.1.

3. **PHARMACEUTICAL FORM**

Solution for infusion.
Clear, colourless to slightly yellow solution.

4. **CLINICAL PARTICULARS**

4.1 **Therapeutic indications**

Lutathera is indicated for the treatment of unresectable or metastatic, progressive, well differentiated (G1 and G2), somatostatin receptor positive gastroenteropancreatic neuroendocrine tumours (GEP-NETs) in adults.

4.2 **Posology and method of administration**

Lutathera should be administered only by persons authorised to handle radiopharmaceuticals in designated clinical settings (see section 6.6) and after evaluation of the patient by a qualified physician.

Before starting treatment with Lutathera, somatostatin receptor imaging (scintigraphy or positron emission tomography [PET]) must confirm the overexpression of these receptors in the tumour tissue with the tumour uptake at least as high as normal liver uptake.
Posology

Adults
The recommended treatment regimen of Lutathera in adults consists of 4 infusions of 7,400 MBq each. The recommended interval between each administration is 8 weeks.

Information on dose modifications to manage severe or intolerable adverse drug reactions is given in the respective section below.

For renal protection purpose, an amino acid solution must be administered intravenously during 4 hours. The infusion of the amino acid solution should start 30 minutes prior to start of Lutathera infusion.

Amino acid solution
The amino acid solution can be prepared as a compounded product, in compliance with the hospital’s sterile medicinal product preparation good practices and according to the composition specified in Table 1.

Table 1. Composition of the compounded amino acid solution

<table>
<thead>
<tr>
<th>Compound</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>L-lysine HCl</td>
<td>25 g*</td>
</tr>

<td>&lt; 1,200 mOsmol/kg</td>
</tr>
</tbody>
</table>

*equivalent to 14.4-20 g lysine
** equivalent to 14.9-20.7 g arginine

An amino acid solution containing just lysine and arginine in the amounts specified in Table 1 is considered the medicinal product of choice, due to its lower total volume to be infused and lower osmolality.

Treatment monitoring
Before each administration and during the treatment, biological tests are required to re-assess the patient’s condition and adapt the therapeutic protocol if necessary (dose, infusion interval, number of infusions).

The minimum laboratory tests needed before each infusion are:
- Haematology (Haemoglobin [Hb], white blood cell count, platelet count)
- Kidney function (serum creatinine and creatinine clearance)
- Liver function (alanine aminotransferase [ALAT], aspartate aminotransferase [ASAT], albumin, bilirubin)
These tests should be performed at least once within 2 to 4 weeks prior to administration, and shortly before the administration. It is also recommended to perform these tests every 4 weeks for at least 3 months after the last infusion of Lutathera and every 6 months thereafter, in order to be able to detect possible delayed adverse reactions (see section 4.8). Dosing may need to be modified based on the test results.

_Dose modification_

Management of severe or intolerable adverse drug reactions may require temporary dose interruption, extending dosing interval from 8 weeks up to 16 weeks, dose reduction, or discontinuation of treatment with Lutathera (see Table 3 and Figure 1).

**Table 3. Recommended dose modifications of Lutathera for Adverse Drug Reactions**

</table>

\(^1\) The same thresholds are also applicable to baseline values at the time of treatment initiation (see section 4.4).

\(^2\) If same thresholds are seen at baseline treatment initiation to be considered after benefit risk assessment (see section 4.4).

* CTCAE: Common Terminology Criteria for Adverse Events, National Cancer Institute

**Figure 1. Scheme of instructions for dose modifications**

![Scheme of instructions for dose modifications](image)

DMT: Dose modifying toxicity

Other reasons to consider temporary dose interruption of Lutathera include occurrence of an intercurrent disease (e.g. urinary tract infection), which according to the physician could increase the risks associated to Lutathera administration, and which should be resolved or stabilized for treatment to resume; and major surgery, in which case treatment should be withheld for 12 weeks after the date of surgery.
**Special populations**

**Elderly**
No dosage adjustment is required in patients 65 years or above as clinical experience has not identified differences in responses between the elderly and younger patients. However, since increased risk of presenting haematotoxicity has been described in elderly patients (≥ 70 years old), a close follow up allowing for prompt dose adaptation (DMT) in this population is advisable.

**Renal impairment**
Careful consideration of the activity to be administered is required since an increased radiation exposure is possible in these patients. The pharmacokinetic profile and safety of lutetium (¹⁷⁷Lu) oxodotreotide in patients with severe renal impairment or end-stage renal disease has not been studied. Treatment with Lutathera in patients with severe kidney failure with creatinine clearance < 30 mL/min is contraindicated (see section 4.3). Treatment with Lutathera in patients with creatinine clearance < 40 mL/min at baseline (using Cockcroft Gault) is not recommended. No dose adjustment is recommended for renally impaired patients with creatinine clearance ≥ 40 mL/min. However, as this medicinal product is known to be substantially excreted by the kidneys, renal function should be more frequently monitored during the treatment as these patients may be at a greater risk of toxicity. For additional details about the treatment of patient with renal impairment see Table 3 in section 4.2 and section 4.4.

**Hepatic impairment**
No dose adjustment is recommended for patients with mild or moderate hepatic impairment. Careful consideration of the activity to be administered to patients with hepatic impairment is required since an increased radiation exposure is possible in these patients. The pharmacokinetic profile of lutetium (¹⁷⁷Lu) oxodotreotide in patients with severe hepatic impairment has not been studied (total bilirubin > 3 times upper limit of normal and any ASAT), therefore those patients should only be treated with Lutathera after careful benefit-risk assessment. For additional details about the treatment of patient with mild to moderate hepatic impairment, see Table 3 and section 4.4.

**Paediatric population**
There is no relevant use of Lutathera in the paediatric population in the indication of treatment of GEP-NETs (excluding neuroblastoma, neuroganglioblastoma, phaeochromocytoma).

**Method of administration**
Lutathera is for intravenous use. It is a ready to use radiopharmaceutical medicinal product for single use only.

Lutathera must be administered by slow intravenous infusion over approximately 30 minutes, concomitantly with amino acid solution administered by contralateral intravenous infusion. This medicinal product must not be injected as a bolus. Premedication with antiemetics should be injected at least 30 minutes prior to the start of amino acid solution infusion to reach the full antiemetic efficacy of the selected product, according to the respective product information.

The recommended infusion method for administration of Lutathera is the gravity method, described in more detail in this section. Treating physicians may use other methods deemed appropriate and safe, including the use of infusion pumps, particularly when dose reduction is required. During the administration the recommended radiation safety precaution measures should be undertaken regardless of the infusion method (see section 6.6).

Lutathera should be infused directly from its original container. The vial must not be opened or the solution transferred to another container. During the administration only disposable materials should be used. The medicinal product should be infused through an intravenous catheter placed in the vein exclusively for its infusion.
Requirements

**Storage of the vial**
- Either in a container made of polymethyl methacrylate (PMMA), a transparent radioprotection container that allows a direct visual inspection of the vial,
- Or in the lead container in which Lutathera is delivered.

**Room and equipment preparation:**
- Administration room:
  - The floor and the furniture should be covered with tissue paper to avoid any accidental contamination
- Medicinal products to be administered:
  - One vial of Lutathera
  - One bag of sodium chloride 9 mg/mL (0.9%) solution for injection (500 mL)
  - Amino acid solution bag(s)
  - Antiemetics
- Care supplies and equipment:
  - Two infusion poles
  - One Long needle (recommended 90 – 100 mm, 18 gauge)
  - One Short needle (recommended 25 mm, 20 gauge)
  - Two gravity intravenous infusion sets with a clamp to regulate or stop the flow (one for Lutathera, one for amino acid solution administration)
  - Two peripheral intravenous plastic catheters
  - One sterile tubing line with a clamp to regulate or stop the flow
  - A pair of tongs (for Lutathera vial handling)
  - Calibrated radioactivity measurement system and Geiger counter to monitor the radioactivity of Lutathera
Lutathera vial tubing connections procedure (see Figure 2):

- The tubing line should be pre-filled with sodium chloride 9 mg/mL (0.9%) solution for injection and then connected with a venous catheter previously inserted to the patient’s arm.
- The infusion set should be connected to the bag of sodium chloride 9 mg/mL (0.9%) solution for injection and pre-filled by opening the clamp.
- The short needle should be inserted into the Lutathera vial, so that it does not touch the radiopharmaceutical solution. This will equilibrate pressure thus reducing any risk of leakage.
- The short needle should be then connected to the pre-filled infusion set.
- The long needle should be connected to the pre-filled tubing line and then inserted into the Lutathera vial, so that it touches the bottom of the vial. This will allow for the complete extraction of the radiopharmaceutical solution.
- The flow of the radiopharmaceutical solution should be regulated with the clamps.

Figure 2. Gravity infusion method - tubing connection scheme
**Administration procedure (gravity method)**

During the infusion, the flow of sodium chloride 9 mg/mL (0.9%) solution for injection increases the pressure in the Lutathera vial, facilitating the flow of Lutathera into the catheter inserted in the patient’s peripheral vein. Careful monitoring of the vital signs during the infusion is recommended.

1. Two intravenous plastic catheters should be inserted into patient’s peripheral veins, one on each arm.
2. The catheters should be connected to the infusion sets (one for Lutathera, one for amino acid solution).
3. Antiemetic premedication should be administered at least 30 minutes prior to the start of amino acid solution infusion (see section 4.2).
4. Administration of the amino acid solution should be initiated 30 minutes before Lutathera infusion, with an infusion rate of 250 to 500 mL/h (depending on volume). Amino acid solution should be administered over 4 hour time span. In case of severe nausea or vomiting during amino acid solution infusion, an antiemetic of a different pharmacological class can be administered.
5. Radioactivity in the Lutathera vial should be measured immediately before infusion using a calibrated radioactivity measurement system.
6. Lutathera infusion should start 30 minutes after the beginning of the amino acid solution infusion, with the infusion rate of approximately 400 mL/h (this infusion rate is the reference rate; the infusion should start at a lower rate of < 100 mL/h for the first 5 to 10 minutes and should then be increased depending on the patient’s venous status). Lutathera should be administered over 30 ± 10 minute time span. Constant intra-vial pressure should be maintained during the entire infusion.
7. Lutathera administration should be initiated by opening first the tubing line connected to the patient’s peripheral vein, and then, by opening the infusion set connected to the bag of sodium chloride 9 mg/mL (0.9%) solution for injection. The pole height should be adjusted in order to compensate any increase or reduction of pressure inside the vial. Moving the patient’s arm position should be avoided if possible (extreme flexion or extension which could lead to vein compression).
8. The flow of Lutathera from the vial to the patient should be monitored during the entire infusion. Soon after the start of the infusion, the radioactivity emission over the patient’s thorax should be measured using Geiger counter to verify the presence of Lutathera in the bloodstream. Subsequent checks of the radioactivity emission should be performed approximately every 5 minutes at the level of the patient’s thorax and vial. During the infusion, the radioactivity emission from the patient’s thorax should steadily increase while the one from the Lutathera vial should decrease.
9. To ensure complete administration, the Lutathera vial should be kept under even pressure. The level of solution in the vial should remain constant during the entire infusion. Visual controls of the solution levels should be repeated during the administration by direct visual control (when PMMA container is used) or using a pair of tongs to handle the vial when the lead shipping container is used.
10. The infusion should be stopped once the radioactivity emission from the vial becomes stable for several minutes (or during two consecutive measurements). This is the only parameter to determine the procedure completion. The volume of sodium chloride 9 mg/mL (0.9%) solution for injection necessary to complete the infusion may vary.
11. Total activity administered is equal to the activity in the vial before infusion minus the activity remaining in the vial after the infusion. The measurements should be performed using a calibrated system.
The following table summarises the required procedures during a treatment course with Lutathera using the gravity method:

**Table 4. Administration procedure of antiemetic, amino acid solution and Lutathera**

For instructions on the medicinal product before administration, see section 12.
For patient preparation, see section 4.4.
For recommendations in case of extravasation, see section 4.4.

### 4.3 Contraindications

- Hypersensitivity to the active substance, to any of the excipients listed in section 6.1.
- Established or suspected pregnancy or when pregnancy has not been excluded (see section 4.6).
- Kidney failure with creatinine clearance < 30 mL/min

### 4.4 Special warnings and precautions for use

**Individual benefit/risk justification**
For each patient, the radiation exposure must be justifiable by the likely benefit. The activity administered should in every case be as low as reasonably achievable to obtain the required therapeutic effect.

Given the mechanism of action and the tolerance profile of Lutathera, it is not recommended to start treatment with Lutathera in patients with somatostatin receptor negative or mixed visceral lesions according to somatostatin receptor imaging.

**Myelosuppression**
Because of the potential for undesirable effects, blood counts must be monitored at baseline and during treatment and until resolution of any eventual toxicity (see section 4.2). Patients with impaired haematological function and patients who have received prior chemotherapy or external beam radiotherapy (involving more than 25% of the bone marrow) may be at higher risk of haematological toxicity during Lutathera treatment. Treatment initiation is not recommended in patients with severely impaired haematological function at baseline (e.g. Hb < 4.9 mmol/L or 8 g/dL, platelets < 75 g/L or 75 x 10^3/mm^3, or leukocytes < 2 g/L or 2000/mm^3) (except lymphopenia).

**Myelodisplastic syndrome and acute leukaemia**
Late-onset myelodisplastic syndrome (MDS) and acute leukaemia (AL) have been observed after treatment with Lutathera (see section 4.8), occurring approximately 28 months (9 – 41) for MDS and 55 months (32 - 125) for AL after the end of treatment. Etiology of this therapy related secondary myeloid neoplasms (t-MNs) is unclear. Factors such as age > 70 years, impaired renal function, baseline cytopenias, prior number of therapies, prior exposure to chemotherapeutic agents (specifically alkylating agents), and prior radiotherapy are suggested as potential risks and/or predictive factors for MDS/AL.
Renal toxicity
Because lutetium (\(^{177}\text{Lu}\)) oxodotreotide is almost exclusively eliminated through the renal system, it is mandatory to concomitantly administer an amino acid solution containing the amino acids L-lysine and L-arginine. The amino acids solution will help to decrease reabsorption of lutetium (\(^{177}\text{Lu}\)) oxodotreotide through the proximal tubules, resulting in a significant reduction in the kidney radiation dose (see section 4.2). When the recommended concomitant amino acids infusion is delivered over a 4 hour time span, a mean reduction in kidney radiation exposure of about 47% has been reported. It is not recommended to decrease the amount of amino acid solution in case of Lutathera dose adaptation.

Patients should be encouraged to empty their bladder as frequently as possible during the administration of amino acids and the hours after administration.
Renal function as determined by serum creatinine and calculated creatinine clearance must be assessed at baseline, during and at least for the first year after treatment (see section 4.2).

Patients with renal impairment at baseline, or with renal or urinary tract morphological abnormalities may be at greater risk of toxicity. Treatment with Lutathera in patients with creatinine clearance < 40 mL/min (using Cockcroft Gault) at baseline is not recommended. More frequent monitoring of renal function is recommended in renally impaired patients with creatinine clearance > 40 mL/min (see section 4.2).

For patients with creatinine clearance < 50 mL/min, an increased risk for transient hyperkalemia due to the amino acid solution should also be taken into consideration (see Warning and precaution regarding the co-administered renal protective amino acid solution).

Hepatic toxicity
Since many patients referred for Lutathera therapy have hepatic metastasis, it may be common to observe patients with altered baseline liver function. Patients with hepatic metastasis or pre-existing advanced hepatic impairment may be at increased risk of hepatotoxicity due to radiation exposure. Therefore, it is recommended to monitor ALAT, ASAT, bilirubin and albumin serum during treatment (see section 4.2).

Patients with baseline liver impairment with either total bilirubinemia > 3 times the upper limit of normal or albuminemia < 30 g/L and prothrombin ratio decreased < 70%, should only be treated with Lutathera after careful benefit-risk assessment (see section 4.2).

Nausea and vomiting
To avoid treatment-related nausea and vomiting, an intravenous bolus of an antiemetic medicinal product should be injected at least 30 minutes prior to the start of amino acid solution infusion to reach the full antiemetic efficacy (see section 4.2).

Concomitant use of somatostatin analogues
Somatostatin and its analogues competitively bind to somatostatin receptors and may interfere with the efficacy of Lutathera (see section 4.5).

Neuroendocrine hormonal crises
Crisis due to excessive release of hormones or bioactive substances may occur following treatment with Lutathera, therefore observation of patients by overnight hospitalisation should be considered in some cases (e.g. patients with poor pharmacologic control of symptoms). In case of hormonal crises, recommended treatments are: intravenous high dose somatostatin analogues, intravenous fluids, corticosteroids, and correction of electrolyte disturbances in patients with diarrhoea and/or vomiting.

Tumour lysis syndrome
Tumour lysis syndrome has been reported following therapy with medicines containing lutetium (\(^{177}\text{Lu}\)). Patients with a history of renal insufficiency and high tumour burden may be at greater risk and should be treated with increased caution. Renal function as well as electrolyte balance should be assessed at baseline and during treatment.
Radioprotection rules
Lutathera should always be infused through an intravenous catheter placed exclusively for its infusion. The adequate position of the catheter should be checked before and during infusion.

The patient treated with Lutathera should be kept away from others during the administration and up to reaching the radiation emission limits stipulated by applicable laws, usually within the 4-5 hours following medicinal product administration. The nuclear medicine physician should determine when the patient can leave the controlled area of the hospital, i.e. when the radiation exposure to third parties does not exceed regulatory thresholds.

The patient should be encouraged to urinate as much as possible after Lutathera administration. Patients should be instructed to drink substantial quantities of water (1 glass every hour) on the day of infusion and the day after to facilitate elimination. The patient should also be encouraged to defecate every day and to use laxative if needed. Urine and faeces should be disposed according to the national regulations.

As long as the patient’s skin is not contaminated, such as from the leakage of the infusion system or because of urinary incontinence, radioactivity contamination is not expected on the skin and in the vomited mass. However, it is recommended that when conducting standard care or exams with medical devices or other instruments which contact the skin (e.g. electrocardiogram (ECG)), basic protection measures should be observed such as wearing gloves, installing the material/electrode before the start of radiopharmaceutical infusion, changing the material/electrode after measurement, and eventually monitoring the radioactivity of equipment after use.

Before the patient is released, the nuclear physician should explain the necessary radioprotection rules of interacting with family members and third parties, and the general precautions the patient must follow during daily activities after treatment (as given in next paragraph and the package leaflet) to minimize radiation exposure to others.

Close contact (less than 1 meter) with other people should be limited for 7 days following an administration of Lutathera. For children and/or pregnant women, close contact (less than 1 meter) should be limited to less than 15 minutes per day for 7 days. Patients should sleep in a separate bedroom from other people for 7 days following an administration of Lutathera. Patients should sleep in separate bedrooms from children and/or pregnant women for 15 days.

Recommended measures in case of extravasation
Disposable waterproof gloves should be worn. The infusion of the medicinal product must be immediately ceased and the administration device (catheter, etc.) removed. The nuclear medicine physician and the radiopharmacist should be informed.

All the administration device materials should be kept in order to measure the residual radioactivity and the activity actually administered and eventually the absorbed dose should be determined. The extravasation area should be delimited with an indelible pen and a picture should be taken if possible. It is also recommended to record the time of extravasation and the estimated volume extravasated. To continue Lutathera infusion, it is mandatory to use a new catheter possibly placing it in a contralateral venous access.

No additional medicinal product can be administered to the same side where the extravasation occurred.

In order to accelerate medicinal product dispersion and to prevent its stagnation in tissue, it is recommended to increase blood flow by elevating the affected arm. Depending on the case, aspiration of extravasation fluid, sodium chloride 9 mg/mL (0.9%) solution for injection flush injection, or applying warm compresses or a heating pad to the infusion site to accelerate vasodilation should be considered.
Symptoms, especially inflammation and/or pain, should be treated. Depending on the situation, the nuclear medicine physician should inform the patient about the risks linked to extravasation injury, and give advice about potential treatment and necessary follow-up requirements. The extravasation area must be monitored until the patient is discharged from the hospital. Depending upon its seriousness, this event should be declared as an adverse reaction.

Patients with urinary incontinence
During the first 2 days following administration of this medicinal product, special precautions should be taken with patients with urinary incontinence to avoid spread of radioactive contamination. This includes the handling of any materials possibly contaminated with urine.

Patients with brain metastases
There is no efficacy data in patients with known brain metastases therefore individual benefit-risk must be assessed in these patients.

Secondary malignant neoplasms
Exposure to ionising radiation is linked with cancer induction and a potential for development of hereditary defects. The radiation dose resulting from therapeutic exposure may result in higher incidence of cancer and mutations. In all cases it is necessary to ensure that the risks of the radiation exposure are less than from the disease itself.

Other patients with risk factors
A patient presenting with any of the conditions below is more prone to develop adverse reactions. Therefore, it is recommended to monitor those patients more frequently during the treatment. Please see Table 3 in case of dose modifying toxicity.

- Bone metastasis;
- Previous oncologic radiometabolic therapies with $^{131}$I compounds or any other therapy using unshielded radioactive sources;
- History of other malignant tumours unless the patient is considered to be in remission for at least 5 years.

Specific warnings
This medicinal product contains up to 3.5 mmol (81.1 mg) sodium per dose, equivalent to 4% of the WHO recommended maximum daily intake of 2 g sodium for an adult.

Precautions with respect to environmental hazard see section 6.6.

Specific warnings and precautions regarding the co-administered renal protective amino acid solution

Hyperkalemia
A transient increase in serum potassium levels may occur in patients receiving arginine and lysine, usually returning to normal levels within 24 hours from the start of the amino acid infusion. Serum potassium levels must be tested before each treatment with amino acid solutions. In case of hyperkalemia, patient’s history of hyperkalemia and concomitant medication should be checked. Hyperkalemia must be corrected accordingly before starting the infusion. In case of pre-existing clinically significant hyperkalemia, a second monitoring prior to amino acid infusion must confirm that hyperkalemia has been successfully corrected. The patient should be monitored closely for signs and symptoms of hyperkalemia, e.g. dyspnea, weakness, numbness, chest pain and cardiac manifestations (conduction abnormalities and cardiac arrhythmias). An electrocardiogram (ECG) should be performed prior to discharging the patient. Vital signs should be monitored during the infusion regardless of baseline serum potassium levels. Patients should be instructed to drink substantial quantities of water (at least 1 glass every hour) on the day of infusion to remain hydrated and facilitate excretion of excess serum potassium. In case hyperkalemia symptoms develop during amino acid infusion, appropriate corrective measures must be taken. In case of severe symptomatic hyperkalemia, discontinuation of amino acid solution infusion should be considered, taking into consideration the risk-benefit of renal protection versus acute hyperkalemia.
Heart failure
Due to potential for clinical complications related to volume overload, care should be taken with use of arginine and lysine in patients with severe heart failure defined as class III or class IV in the NYHA classification (New York Heart Association). Patients with severe heart failure defined as class III or class IV in the NYHA classification should only be treated after careful benefit-risk assessment, taking into consideration volume and osmolality of the amino acid solution.

Metabolic acidosis
Metabolic acidosis has been observed with complex amino-acid solutions administered as part of total parenteral nutrition (TPN) protocols. Shifts in acid-base balance alter the balance of extracellular-intracellular potassium and the development of acidosis may be associated with rapid increases in plasma potassium.

4.5 Interaction with other medicinal products and other forms of interaction

Somatostatin and its analogues competitively bind to somatostatin receptors and may interfere with the efficacy of Lutathera. Therefore, administration of long acting somatostatin analogues should be avoided within 30 days prior to the administration of this medicinal product. If necessary, patients may be treated with short acting somatostatin analogues until at least 24 hours preceding Lutathera administration.

There is some evidence that corticosteroids can induce down-regulation of SST2 receptors. Therefore, as a matter of cautiousness, repeated administration of high-doses of glucocorticosteroids should be avoided during Lutathera treatment. Patients with a history of chronic use of glucocorticosteroids should be carefully evaluated for sufficient somatostatin receptor expression. It is not known if there is of interaction between glucocorticosteroids used intermittently for the prevention of nausea and vomiting during Lutathera administration. Therefore, glucocorticosteroids should be avoided as preventive anti-emetic treatment. In the case where the treatments previously provided for nausea and vomiting are insufficient, a single dose of corticosteroids can be used, as long as it is not given before initiating or within one hour after the end of Lutathera infusion.

The absence of inhibition or significant induction of the human CYP450 enzymes, the absence of specific interaction with P-glycoprotein (efflux transporter) as well as OAT1, OAT3, OCT1, OCT2, OATP1B1, OATP1B3 and BCRP transporters in pre-clinical studies suggest that Lutathera has a low probability of causing significant other drug-drug interactions.

4.6 Fertility, pregnancy and lactation

Women of childbearing potential
When an administration of radiopharmaceuticals to a woman of childbearing potential is intended, it is important to determine whether or not she is pregnant. Any woman who has missed a period should be assumed to be pregnant until proven otherwise. If in any doubt about her potential pregnancy (if the woman has missed a period, if the period is very irregular, etc.), alternative techniques not using ionising radiation (if there are any) should be offered to the patient. Before the use of Lutathera, pregnancy should be excluded using an adequate/validated test.

Contraception in males and females
Lutathera can cause fetal harm when administered to a pregnant woman. During treatment with Lutathera and for a minimum of the following 6 months after the end of the treatment, appropriate measures must be taken to avoid pregnancy; this applies to patients of both genders.

Pregnancy
No studies on animal reproductive function have been conducted with lutetium (177Lu) oxodotreotide.
Radionuclide procedures carried out on pregnant women also involve radiation dose to the foetus. The use of Lutathera is contraindicated during established or suspected pregnancy or when pregnancy has not been excluded due to the risk associated with the ionizing radiation (see section 4.3). Pregnant women should be advised of the risk to a foetus.

**Breast-feeding**
It is unknown whether lutetium \(^{177}\text{Lu}\) oxodotreotide is excreted in breast milk. A risk to the suckling child associated with ionising radiation cannot be excluded. Breast-feeding should be avoided during treatment with this medicinal product. If treatment with Lutathera during breast-feeding is necessary, the child must be weaned.

**Fertility**
No animal studies have been performed to determine the effects of lutetium \(^{177}\text{Lu}\) oxodotreotide on the fertility of either gender. Ionizing radiations of lutetium \(^{177}\text{Lu}\) oxodotreotide may potentially have temporary toxic effects on female and male gonads. Genetic consultation is recommended if the patient wishes to have children after treatment. Cryopreservation of sperm or eggs can be discussed as an option to patients before the treatment.

### 4.7 Effects on ability to drive and use machines
Lutathera has no or negligible influence on the ability to drive and use machines. Nevertheless, the general condition of the patient and the possible adverse reactions to treatment must be taken into account before driving or using machines.

### 4.8 Undesirable effects

**Summary of safety profile**
The overall safety profile of Lutathera is based on pooled data from patients from clinical trials (NETTER-1 phase III and Erasmus phase I/II Dutch patients) and from compassionate use programs.

The most common adverse reactions in patients receiving Lutathera treatment were nausea and vomiting which occurred at the beginning of the infusion in 58.9% and 45.5% of patients, respectively. The causality of nausea / vomiting is confounded by the emetic effect of the concomitant amino acids infusion administered for renal protection.

Due to the bone marrow toxicity of Lutathera, the most expected adverse reactions were related to haematological toxicity: thrombocytopenia (25%), lymphopenia (22.3%), anaemia (13.4%), pancytopenia (10.2%).

Other very common adverse reactions reported include fatigue (27.7%) and decreased appetite (13.4%).

**Tabulated list of adverse reactions**
The adverse reactions are listed in Table 5 according to the frequency and the MedDRA System Organ Class (SOC). The frequencies are categorized as follows: very common (≥1/10), common (≥1/100 to <1/10), uncommon (≥1/1,000 to <1/100), rare (≥1/10,000 to <1/1,000), very rare (<1/10,000) and not known (cannot be estimated from the available data).
Table 5. Frequency of adverse reactions reported from clinical trials and from post-marketing surveillance

</table>

**Description of selected adverse reactions**

**Bone marrow toxicity**

Bone marrow toxicity (myelo-/hematotoxicity) manifested with reversible / transient reductions in blood counts affecting all lineages (cytopenias in all combinations, i.e., pancytopenia, bicytopenias, isolated monocytopenias – anemia, neutropenia, lymphocytopenia, and thrombocytopenia). In spite of an observed significant selective B-cell depletion, no increase in the rate of infectious complications occurs after PRRT. Cases of irreversible hematological pathologies, i.e., premalignant and malignant blood neoplasms (i.e., myelodysplastic syndrome and acute myeloid leukemia, respectively) have been reported following Lutathera treatment.

**Nephrotoxicity**

Lutetium (\(^{177}\)Lu) oxodotreotide is excreted by the kidney. The long-term trend of progressive glomerular filtration function deterioration demonstrated in the clinical studies confirms that Lutathera-related nephropathy is a chronic kidney disease that develops progressively over months or years after exposure. An individual benefit-risk assessment is recommended prior to treatment with Lutathera in patients with mild and moderate renal impairment, for additional details see section 4.2 (Table 3) and section 4.4. The use of Lutathera is contraindicated in patients with severe kidney failure (see section 4.3).

**Hormonal crises**

Hormonal crises related to bioactive substances release (probably due to lysis of the neuroendocrine tumour cells) have rarely been observed and resolved after appropriate medical treatment (section 4.4).

**Reporting of suspected adverse reactions**

Reporting suspected adverse reactions after authorisation of the medicinal product is important. It allows continued monitoring of the benefit/risk balance of the medicinal product. Healthcare professionals are asked to report any suspected adverse reactions via the national reporting system listed in Appendix V.
4.9 Overdose

Overdose is unlikely with Lutathera as this medicinal product is supplied as a “single dose” and “ready to use” product containing a predefined amount of radioactivity. In the case of overdose, an increase in the frequency of the adverse reactions related to radiotoxicity is expected.

In the event of administration of a radiation overdose with Lutathera, the absorbed dose to the patient should be reduced where possible by increasing the elimination of the radionuclide from the body by frequent micturition or by forced diuresis and frequent bladder voiding during the first 48 hours after infusion. It is helpful to estimate the effective dose that was applied.

The following checking should be carried out every week, for the next 10 weeks:

- Hematologic monitoring: white blood cells, platelets, and haemoglobin
- Blood chemistry monitoring: serum creatinine and glycæmia.

5. PHARMACOLOGICAL PROPERTIES

5.1 Pharmacodynamic properties

Pharmacotherapeutic group: Other therapeutic radiopharmaceuticals, ATC code: V10XX04

**Mechanism of action**

Lutetium (177Lu) oxodotreotide has a high affinity for subtype 2 somatostatin receptors (sst2). It binds to malignant cells which overexpress sst2 receptors. Lutetium-177 (177Lu) is a β-emitting radionuclide with a maximum penetration range in tissue of 2.2 mm (mean penetration range of 0.67 mm), which is sufficient to kill targeted tumour cells with a limited effect on neighbouring normal cells.

**Pharmacodynamic effects**

At the concentration used (about 10 μg/mL in total, for both free and radiolabeled forms), the peptide oxodotreotide does not exert any clinically relevant pharmacodynamic effect.

**Clinical efficacy and safety**

NETTER-1 phase III study was a multicentre stratified, open labelled, randomized, comparator-controlled, parallel-group study comparing treatment with Lutathera (4 doses of 7,400 MBq every 8 weeks) co-administered with amino acid solution plus best supportive care (BSC; octreotide long acting release [LAR] 30 mg every 4 weeks for symptoms control, replaced by short acting octreotide in the 4 weeks interval before Lutathera administration) to high dose octreotide LAR (60 mg every 4 weeks) in patients with inoperable, progressive, somatostatin receptor positive, midgut carcinoid tumours. The primary endpoint for the study was progression-free survival (PFS) evaluated by response evaluation criteria in solid tumours (RECIST 1.1), based on independent radiology assessment. Secondary endpoints included objective response rate (ORR), overall survival (OS), time to tumour progression (TTP), safety and tolerability of the medicinal product and quality of life (QoL). Two hundred twenty-nine (229) patients have been randomized to receive either Lutathera (n=116) or high dose 60 mg octreotide LAR (n=113). Demographics as well as patients and disease characteristics were well balanced between groups with a median age of 64 years and 82.1% Caucasian in the general population.

At the time of final per-protocol PFS statistical analysis (cut–off date 24 July 2015), the number of centrally confirmed disease progressions or deaths was 21 events in the Lutathera arm and 70 events in the octreotide LAR arm (Table 6). PFS differed significantly (p<0.0001) between the treatment groups. The median PFS for Lutathera was not reached at the time of analysis whereas the one of octreotide LAR was 8.5 months. The hazard ratio for Lutathera was 0.18 (95% CI: 0.11 - 0.29), indicating 82% reduction in the risk for a patient to progress or die under Lutathera compared to octreotide LAR.
Table 6. PFS observed in the NETTER-1 phase III study in patients with progressive midgut carcinoid tumour – cut-off date 24 July 2015 (full analyses set (FAS), N=229)

Figure 3. PFS Kaplan Meier curves of patients with progressive midgut carcinoid tumour - cut-off date 24 July 2015 (NETTER-1 phase III study; FAS, N=229)

At the cut-off date for post-hoc statistical analysis (30 June 2016), the number of centrally confirmed disease progressions or deaths was 30 events in the Lutathera arm and 78 events in the octreotide LAR arm (Table 7). PFS differed significantly (p<0.0001) between the treatment groups. The median PFS for Lutathera was 28.4 months whereas the one of octreotide LAR was 8.5 months. The hazard ratio for Lutathera was 0.21 (95% CI: 0.14 - 0.33), indicating 79% reduction in the risk for a patient to progress or die under Lutathera compared to octreotide LAR.

The PFS Kaplan-Meier graph for the full analysis set (FAS) at the cut-off date 30 June 2016 is depicted in Figure 4.

Figure 4. PFS Kaplan Meier curves of patients with progressive midgut carcinoid tumour - cut-off date 30 June 2016 (NETTER-1 phase III study; FAS, N=231)

With respect to overall survival OS, at the time of interim analysis (24 July 2015), there were 17 deaths in the Lutathera arm and 31 in octreotide LAR 60 mg arm and the hazard ratio was 0.459 in favour of Lutathera, but did not reach the level of significance for interim analysis (HR 99.9915% CI: 0.140, 1.506). OS median was 27.4 months in octreotide LAR arm and was not reached in Lutathera arm. An update conducted about one year after (30 June 2016) showed similar trend with 28 deaths in the Lutathera arm and 43 in octreotide LAR 60 mg arm, an HR of 0.536, and a median OS of 27.4 months in octreotide LAR arm and still not reached in Lutathera arm. The final OS analysis is foreseen after 158 cumulative deaths.

Health Related Quality of Life (HRQOL) was assessed using the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30) (generic instrument) and its neuroendocrine tumour module (EORTC QLQ-GI.NET-21). The results indicate an improvement in the overall global health-related quality of life up to week 84, for patients on Lutathera treatment as compared to patients on Octreotide LAR.

Erasmus phase I/II study was a monocentric single arm open-label study to evaluate the efficacy of Lutathera (7,400 MBq administered for 4 times every 8 weeks) co-administered with amino acid solution in patients with somatostatin receptor positive tumours. The mean age of patients enrolled in the study was 60 years. Most patients were Dutch (811) with the remaining (403) residents of various European and non-European countries. The main analysis has been conducted on 811 Dutch patients with different somatostatin receptor positive tumour types. The ORR (including complete response (CR) and partial response (PR) according to RECIST criteria) and duration of response (DoR) for the FAS Dutch population with gastroenteropancreatic (GEP) and bronchial NETs (360 patients) as well as per tumour type are presented in Table 8.
Table 8. Best response, ORR and DoR observed in the Erasmus phase I/II study in Dutch patients with GEP and bronchial NETs – (FAS, N=360)

* Includes Foregut, Midgut and Hindgut; **Foregut NETs other than bronchial and pancreatic

In the Erasmus phase I/II study 188 patients (52%) received and 172 (48%) did not receive concomitant octreotide LAR during Lutathera treatment. No statistically significant difference in PFS was observed between the subgroup of patients who did not receive octreotide LAR (25.4 months [95% CI 22.8-30.6]) versus the subgroup who did receive concomitant treatment with octreotide LAR (30.9 months [95% CI 25.6-34.8]) (p= 0.747).

Paediatric population
The European Medicines Agency has waived the obligation to submit the results of studies with Lutathera in all subsets of the paediatric population in the treatment of GEP-NETs (excluding neuroblastoma, neuroganglioblastoma, phaeochromocytoma). See section 4.2.
5.2 Pharmacokinetic properties

**Absorption**
The medicinal product is administered intravenously and is immediately and completely bioavailable.

**Organ uptake**
At 4 hours after administration, the distribution pattern of lutetium (\(^{177}\)Lu) oxodotreotide shows a rapid uptake in kidneys, tumour lesions, liver and spleen, and in some patients in the pituitary gland and in the thyroid. The co-administration of amino acid solution decreases the kidney uptake, enhancing the elimination of radioactivity (see section 4.4). Biodistribution studies show that lutetium (\(^{177}\)Lu) oxodotreotide is rapidly cleared from the blood. An analysis performed with human plasma to determine the extent of plasma protein binding of non-radioactive compound (lutetium (\(^{175}\)Lu) oxodotreotide) showed that about 50% of the compound is bound to plasmatic proteins. Transchelation of lutetium from lutetium (\(^{175}\)Lu) oxodotreotide into serum proteins has not been observed.

**Biotransformation**
There is evidence, from the analysis of urine samples of 20 patients included in the NETTER-1 phase III Dosimetry, pharmacokinetic and ECG substudy, that lutetium (\(^{177}\)Lu) oxodotreotide is poorly metabolized and is excreted mainly as intact compound by renal route.

The high performance liquid chromatography (HPLC) analyses performed on urine samples collected up to 48 hours post infusion showed lutetium (\(^{177}\)Lu) oxodotreotide radiochemical purity close to 100% in most of the analysed samples (with lowest radiochemical purity value being greater than 92%), indicating that the compound is eliminated in urine mainly as intact compound. This evidence confirms what has been previously observed in the Erasmus phase I/II study, in which HPLC analysis of a urine specimen collected 1 hour post administration of lutetium (\(^{177}\)Lu) oxodotreotide from one patient receiving 1.85 MBq of lutetium (\(^{177}\)Lu) oxodotreotide indicated that the main portion (91%) was excreted unchanged. These findings are supported by in vitro metabolism data in human hepatocytes, in which no metabolic degradation of lutetium (\(^{175}\)Lu) oxodotreotide was observed.

**Elimination**
Based on the data collected during the Erasmus phase I/II and NETTER-1 phase III studies, lutetium (\(^{177}\)Lu) oxodotreotide is primarily eliminated by renal excretion: about 60% of the medicinal product is eliminated in the urine within 24 hours, and about 65% within 48 hours following the administration.

**Elderly**
The pharmacokinetics profile in elderly patients (\(\geq 75\) years) has not been established. No data are available.

5.3 Preclinical safety data

Toxicological studies with rats have demonstrated that a single intravenous injection of up to 4,550 MBq/kg was well tolerated and no deaths were observed. When testing the cold compound (non-radioactive lutetium (\(^{175}\)Lu) oxodotreotide) as a single intravenous injection in rats and dogs at doses up to 20,000 µg/kg (rats) and 3,200 µg/kg (dogs), the compound was well tolerated in both species and no deaths were observed. Toxicity with four repeated administrations, once every 2 weeks, of 1,250 µg/kg of the cold compound in rats and 80 µg/kg in dogs was not observed. This medicinal product is not intended for regular or continuous administration.

Mutagenicity studies and long-term carcinogenicity studies have not been carried out. Non-clinical data on the cold compound (non-radioactive lutetium (\(^{175}\)Lu) oxodotreotide) reveal no special hazard for humans based on conventional studies of safety pharmacology, repeated dose toxicity, genotoxicity.

Acetic acid
Sodium acetate
Gentisic acid
Ascorbic acid
Pentetic acid
Sodium chloride
Sodium hydroxide
Water for injections

6.2 Incompatibilities

This medicinal product must not be mixed with other medicinal products except those mentioned in section 4.2.

6.3 Shelf life

72 hours from the date and time of calibration.

6.4 Special precautions for storage

Store below 25°C.
Store in the original package to protect from ionizing radiation (lead shielding).
Storage of radiopharmaceuticals should be in accordance with national regulation on radioactive materials.

6.5 Nature and contents of container

Clear colourless Type I glass vial, closed with a bromobutyl rubber stopper and aluminium seal.
Each vial contains a volume varying from 20.5 to 25.0 mL of solution corresponding to an activity of 7,400 MBq at date and time of infusion.
The vial is enclosed within a lead container for protective shielding.

6.6 Special precautions for disposal and other handling

For single use only.

General warning
Radiopharmaceuticals should be received, used and administered only by authorised persons in designated clinical settings. Their receipt, storage, use, transfer and disposal are subject to the regulations and/or appropriate licences of the competent official organisation.

Radiopharmaceuticals should be prepared in a manner which satisfies both radiation safety and pharmaceutical quality requirements. Appropriate aseptic precautions should be taken.

For instruction on preparation of the medicinal product before administration, see section 12.

If at any time in the preparation of this medicinal product the integrity of this container and vial is compromised it should not be used.

Administration procedures should be carried out in a way to minimise risk of contamination of the medicinal product and irradiation of the operators. Adequate shielding is mandatory.
It is necessary to wear waterproof gloves and suitable aseptic techniques when handling the medicinal product.
The administration of radiopharmaceuticals creates risks for other persons from external radiation or contamination from spill of urine, vomiting etc. Radiation protection precautions in accordance with national regulations must therefore be taken.

The surface dose rates and the accumulated dose depend on many factors. Measurements on the location and during work are critical and should be practiced for more precise and instructive determination of overall radiation dose to the staff. Healthcare personnel are advised to limit the time of close contact with patients injected with Lutathera. The use of television monitor systems to monitor the patients is recommended. Given the half-life of $^{177}$Lu it is specially recommended to avoid internal contamination. It is necessary to use protective high quality (latex/nitrile) gloves to avoid direct contact with the radiopharmaceutical (vial/syringe). For minimising radiation exposure, always use the principles of time, distance and shielding (reducing the manipulation of the vial and using the material already supplied par the manufacturer).

This preparation is likely to result in a relatively high radiation dose to most patients. The administration of 7,400 MBq may result in significant environmental hazard. This may be of concern to the immediate family of those individuals undergoing treatment or the general public depending on the level of activity administered, hence radioprotection rules should be followed (section 4.4). Suitable precautions in accordance with national regulations should be taken concerning the activity eliminated by the patients in order to avoid any contaminations.

Any unused medicinal product or waste material should be disposed according to local requirements.

7. MARKETING AUTHORISATION HOLDER

Advanced Accelerator Applications
20 rue Diesel
01630 Saint Genis Pouilly

8. MARKETING AUTHORISATION NUMBER(S)

EU/1/17/1226/001

9. DATE OF FIRST AUTHORISATION/RENEWAL OF THE AUTHORISATION

Date of first authorisation: 26 September 2017

10. DATE OF REVISION OF THE TEXT
11. DOSIMETRY

The following conclusions on treatment with Lutathera were determined from radiation dosimetry evaluations performed in clinical studies:

- The critical organ is the bone marrow, however, with the recommended Lutathera cumulative dose of 29,600 MBq (4 administrations of 7,400 MBq), no correlation between hematologic toxicity and the total radioactivity administered or bone marrow absorbed dose has been observed either in Erasmus phase I/II or in NETTER-1 phase III study.

- Kidney is not a critical organ if a co-infusion of an appropriate amino acids solution is performed.

Overall, the results of the dosimetric analysis performed in the NETTER-1 phase III dosimetry substudy and in the Erasmus phase I/II study are in agreement and indicate that Lutathera dose regimen (4 administrations of 7,400 MBq) is safe.

Table 10. Absorbed dose estimates for lutetium (\(^{177}\)Lu) oxodotreotide from NETTER-1 phase III study (Olinda output)

*n=11 (male patients only)  
**n=9 (female patients only)
Radiation dose to specific organs, which may not be the target organ of therapy, can be influenced significantly by pathophysiological changes induced by the disease process. This should be taken into consideration when using the following information.

12. **INSTRUCTIONS FOR PREPARATION OF RADIOPHARMACEUTICALS**

**Quality controls**

The solution should be visually inspected for damage and contamination before use, and only clear solutions free of visible particles should be used. The visual inspection of the solution should be performed under a shielded screen for radioprotection purposes. The vial must not be opened.

If at any time in the preparation of this medicinal product the integrity of this vial is compromised, it should not be used.

The amount of radioactivity in the vial must be measured prior to infusion using a suitable radioactivity calibration system in order to confirm that the actual amount of radioactivity to be administered is equal to the planned amount at the infusion time.

Any unused medicinal product or waste material should be disposed of in accordance with local requirements (see section 6.6).

ANNEX II

A. MANUFACTURERS RESPONSIBLE FOR BATCH RELEASE

B. CONDITIONS OR RESTRICTIONS REGARDING SUPPLY AND USE

C. OTHER CONDITIONS AND REQUIREMENTS OF THE MARKETING AUTHORISATION

D. CONDITIONS OR RESTRICTIONS WITH REGARD TO THE SAFE AND EFFECTIVE USE OF THE MEDICINAL PRODUCT
A. MANUFACTURERS RESPONSIBLE FOR BATCH RELEASE

Name and address of the manufacturers responsible for batch release

Advanced Accelerator Applications Ibérica, S.L.U.
Polígono Industrial la Cuesta – Sector 3
Parcelas 1 y 2 La Almunia de Doña Godina
50100 Zaragoza
Spain

Advanced Accelerator Applications (Italy) S.r.l
Via Ribes 5
10010 Colleretto Giacosa (TO)
Italy

The printed package leaflet of the medicinal product must state the name and address of the manufacturer responsible for the release of the concerned batch.

B. CONDITIONS OR RESTRICTIONS REGARDING SUPPLY AND USE

Medicinal product subject to restricted medical prescription (see Annex I: Summary of Product Characteristics, section 4.2).

C. OTHER CONDITIONS AND REQUIREMENTS OF THE MARKETING AUTHORISATION

- Periodic safety update reports (PSURs)

The requirements for submission of PSURs for this medicinal product are set out in the list of Union reference dates (EURD list) provided for under Article 107c(7) of Directive 2001/83/EC and any subsequent updates published on the European medicines web-portal.

The marketing authorisation holder (MAH) shall submit the first PSUR for this product within 6 months following authorisation.

D. CONDITIONS OR RESTRICTIONS WITH REGARD TO THE SAFE AND EFFECTIVE USE OF THE MEDICINAL PRODUCT

- Risk management plan (RMP)

The marketing authorisation holder (MAH) shall perform the required pharmacovigilance activities and interventions detailed in the agreed RMP presented in Module 1.8.2 of the marketing authorisation and any agreed subsequent updates of the RMP.

An updated RMP should be submitted:
- At the request of the European Medicines Agency;
- Whenever the risk management system is modified, especially as the result of new information being received that may lead to a significant change to the benefit/risk profile or as the result of an important (pharmacovigilance or risk minimisation) milestone being reached.
**Additional risk minimisation measures**

Prior to launch of Lutathera in each Member State the marketing authorisation holder (MAH) must agree about the content and format of the educational programme, including communication media, distribution modalities, and any other aspects of the programme, with the National Competent Authority.

The educational programme is aimed at increasing patients’ awareness on the risk of radiotoxicity by occupational exposure and inadvertent exposure to peptide receptor radionuclide therapy, and at providing information concerning the necessary precautions to take to limit unnecessary exposure to themselves and the people around them.

The MAH shall ensure that in each Member State where Lutathera is marketed, all patients/carers who are expected to be administered Lutathera have access to/are provided with a patient educational material containing:

- The package leaflet
- Patient guide

**The patient guide** shall contain the following key elements:

- Brief introduction to the treatment and the administration procedure
- Information on the precautions the patient should take before, during and after the administration procedure, at the hospital and at home, to limit unnecessary exposure to radiations of themselves and their entourage.
- Information that PPRT can cause serious side effects during or after treatment and that any side effect should be reported to the physician.

B. PACKAGE LEAFLET
This medicine is subject to additional monitoring. This will allow quick identification of new safety information. You can help by reporting any side effects you may get. See the end of section 4 for how to report side effects.

Read all of this leaflet carefully before you are given this medicine because it contains important information for you.
- Keep this leaflet. You may need to read it again.
- If you have any further questions, ask your nuclear medicine doctor who will supervise the procedure.
- If you get any side effects, talk to your nuclear medicine doctor. This includes any possible side effects not listed in this leaflet. See section 4.

What is in this leaflet

1. What Lutathera is and what it is used for
2. What you need to know before Lutathera is used
3. How Lutathera is used
4. Possible side effects
5. How Lutathera is stored
6. Contents of the pack and other information

1. What Lutathera is and what it is used for

Lutathera is a radiopharmaceutical medicine used for the treatment of certain tumours (gastroenteropancreatic neuroendocrine tumours), which cannot be completely removed from your body by surgery, have spread in your body (metastatic) and does not respond more to your current treatment. The tumour needs to have somatostatin receptors on the surface of its cells in order for the medicine to be effective. Lutathera binds with these receptors and emits radioactivity directly into the tumour cells, causing their death.

The use of Lutathera does involve exposure to amounts of radioactivity. Your doctor and the nuclear medicine doctor have considered that the clinical benefit that you will obtain from the procedure with the radiopharmaceutical outweighs the risk due to radiation.

In addition to administration of Lutathera, an infusion with amino acids will be given to you in order to protect your kidneys as well as medicines (antiemetics) to avoid nausea and vomiting that may be caused by amino acid infusion.

2. What you need to know before Lutathera is used

Lutathera must not be used
- if you are allergic to lutetium (\(^{177}\)Lu) oxodotreotide or any of the other ingredients of this medicine (listed in section 6)
- if you are pregnant or think you may be pregnant or it is not confirmed if you are pregnant
- if your kidneys are seriously impaired
Warnings and precautions
Talk to your doctor before you are given Lutathera as it may cause:
- secondary blood cancer (myelodisplastic syndrome or acute leukaemia) which can rarely occur several years after you have completed Lutathera treatment.

If any of these apply to you, tell your doctor or pharmacist or healthcare provider before receiving Lutathera, as well as during treatment with Lutathera:
- If you had or have weakness, fatigue, shortness of breath, poor concentration, frequent infections, fever, easily bleeding or difficulty to stop bleeding (signs and symptoms of myelosuppression). Tell your doctor if you had other type of cancer within the last 5 years, bone metastasis, previous anti-cancer treatment (chemotherapy) or radiation therapy.
- If you had or have swollen feet and ankle, too much urine or not enough urine, itching or trouble catching your breath (signs and symptoms of chronic kidney disease).
- If you had or have any itchy yellow skin or if the whites of your eye turn yellow, nausea or vomiting, fatigue, loss of appetite, pain in the upper right side of your stomach area (abdomen), dark or brown urine, or you bleed or bruise more easily than normal (signs and symptoms of liver disease).
- If you have breathlessness, weakness, numbness, chest pain, palpitations or abnormal heart rhythm (signs and symptoms of high potassium levels in blood (hyperkalemia)).
- If you have breathlessness, difficulty breathing when lying down or swelling of the feet or legs (signs and symptoms of heart failure).
- If you have breathlessness, difficulty breathing when lying down or swelling of the feet or legs (signs and symptoms of heart failure).
- If you have breathlessness, difficulty breathing when lying down or swelling of the feet or legs (signs and symptoms of heart failure).
- If your kidney or urinary tract is not correctly developed.
- If you are suffering from urinary incontinence.

Treatment with Lutathera (lutetium (\(^{177}\text{Lu}\)) oxodotreotide) may cause tumour lysis syndrome, due to the rapid breakdown of tumour cells. This may result in abnormal blood test results, irregular heartbeat, kidney failure or seizures within a week of treatment. Your doctor will perform blood tests to monitor you for this syndrome. Tell your doctor if you have muscle cramping, muscle weakness, confusion, or shortness of breath.

Unless your doctor has considered that the clinical benefit of the treatment overcomes the possible risks, you will not be given this medicine:
- if you have received a previous external radiation therapy on more than 25% of your bone marrow
- if you heart is seriously impaired
- if you have seriously affected blood cell counts
- if your liver is seriously impaired
- if it appears that your tumour does not have sufficient somatostatin receptors

Children and adolescents
The safety and efficacy of this medicine has not yet been established in children and adolescents under 18 years of age. Talk to your nuclear medicine doctor if you are under 18 years old.

Other medicines and Lutathera
Tell your nuclear medicine doctor if you are taking, have recently taken or might take any other medicines including somatostatin analogues, glucocorticoids (also called corticosteroids), since they may interfere with your treatment. If you are taking somatostatin analogues you might be asked to stop and/or adapt your treatment for a short period of time.

Pregnancy, breast-feeding and fertility
If you are pregnant or breast-feeding, think you may be pregnant or are planning to have a baby, ask your nuclear medicine doctor for advice before you are given this medicine.

Lutathera is contraindicated in pregnant women, as ionizing radiation is dangerous for the foetus. Breast-feeding should be avoided during treatment with this medicinal product. If treatment with Lutathera during breast-feeding is necessary, the child must be weaned.
You must inform the nuclear medicine doctor before the administration of Lutathera if there is a possibility you might be pregnant or if you have missed your period or if you are breast-feeding. When in doubt, it is important to consult your nuclear medicine doctor who will supervise the procedure.

During treatment with Lutathera and for a minimum of the following 6 months after the end of the treatment, appropriate measures must be taken to avoid pregnancy; this applies to patients of both genders.

Fertility
Ionizing radiations of the medicine may potentially decrease your fertility. Genetic consultation is recommended if you wish to have children after treatment. Cryopreservation of sperm or eggs may be offered to you before the treatment.

Driving and using machines
It is considered unlikely that Lutathera will affect your ability to drive or to use machines; however, your general condition and the possible adverse reactions to treatment must be taken into account to assess this ability before driving or using machines.

Lutathera contains sodium
This medicine contains up to 81.1 mg sodium (main component of cooking/table salt) in each vial. This is equivalent to 4% of the recommended maximum daily dietary intake of sodium for an adult.

3. How Lutathera is used

There are strict laws on the use, handling and disposal of radiopharmaceutical products. Lutathera will only be used in special controlled areas. This medicine will only be handled and given to you by people who are trained and qualified to use it safely. These persons will take special care for the safe use of this medicine and will keep you informed of their actions.

The recommended dose is 7,400 MBq (megabecquerel, the unit used to express radioactivity) in a single infusion, which is given at 4 times once every 8 weeks.

Administration of Lutathera and conduct of the procedure
Lutathera is administered directly into a vein.

Due to the radiation emitted by this medicine, during the administration procedure, you should be isolated from other patients who are not receiving the same treatment. The doctor will inform you when you can leave the controlled area or the hospital.

In addition to administration of Lutathera, an infusion with amino acids will be given to you in order to protect your kidneys. This might induce nausea and vomiting; you will also receive an injection before the start of the treatment to reduce these symptoms.

Duration of the procedure
Your nuclear medicine doctor will inform you about the usual duration of the procedure. The medicine infusion takes 30 ±10 minutes; but the complete administration procedure will take approximately 5 hours. This treatment is given in 4 treatment cycles which are separated by 8 to 16 weeks. Your doctor will regularly monitor your condition to check that the treatment is having the desired effect.
**Treatment monitoring**
Treatment with Lutathera can have an impact on blood cells, liver and kidneys (see section 4). In consequence, your doctor will ask you to have regular blood tests in order to check your eligibility for this treatment and to detect any side effects as early as possible. Based on the results, your doctor may decide to delay or stop your treatment with this medicine if necessary.

**After administration of Lutathera**
You will be requested to drink a sufficient amount of water (1 glass every hour) necessary to urinate every hour on the day of infusion and the day after, and try to defecate every day, in order to eliminate the medicine from your body.
Because this medicine is radioactive, you will have to follow the instructions described below to minimize radiation exposure to others.
Considering current knowledge and experience in this field and the physical and pharmaceutical properties of the medicine, it is estimated that the health risks to your family members and the general public are low. However, you must adhere to the following rules to maximize the safety of other persons. These rules are the result of many years of experience in the use of radioactivity in medicine, and they include recommendations issued by international organizations.

**General rule**
You should limit close contact with people who live with you by keeping a distance of at least one meter for 7 days after you receive Lutathera.

**Use of toilets**
Toilets must be used in a seated position, even for men. It is absolutely necessary to use toilet paper each time. It is also important to wash your hands to avoid contaminating the door handles. It is strongly recommended to move your bowels every day and use a laxative if necessary. Furthermore, drink frequently and try to urinate every hour on the day you received treatment and on the day after. Follow your doctor’s advice on how much fluid to drink.

**Contact with children and/or pregnant women**
After your receive Lutathera, it is strongly recommended that you limit close contact (less than 1 meter) with children and/or pregnant women to less than 15 minutes per day for 7 days.

**Contact with spouse and people in the family circle**
You should sleep in a separate bedroom from other people for 7 days after you receive Lutathera. You should sleep in separate bedrooms from children and/or pregnant women for 15 days after you receive Lutathera.

**Breast-feeding**
Breast-feeding must be stopped. If treatment with Lutathera during breast-feeding is necessary, the child must be weaned.

**Pregnancy**
Ionizing radiation is dangerous for the foetus, therefore pregnancy is contraindicated. Men and women of child-bearing potential must refrain from procreation by using effective contraceptive methods during the treatment and for 6 months after.

**People who need extra assistance**
People who are confined to the bed or have reduced mobility will preferably receive assistance by a care provider. It is recommended that when providing assistance in the bathroom, the care provider wears disposable gloves for 7 days after administration. In the case of the use of special medical equipment such as catheters, colostomy bags bedpan, water nozzle, or anything that could be contaminated by your body fluids these must be emptied immediately in the toilet and then cleaned. If anyone helps you clean up vomit, blood, urine, or stool they should wear plastic gloves; the gloves should then be disposed of in a specific trash plastic bag (according to the recommendation stated in section "Trash recommendations" below).
Dishes and bathroom accessories
Take special precautions during the 7 days after treatment:
- Flush all wipes and/or toilet paper down the toilet immediately after use,
- Always wash your hands well after using the toilet,
- Take a shower every day,
- Flush any tissues or any other items that contain anything from your body, such as blood, urine and faeces down the toilet. Items that cannot be flushed down the toilet, such as menstrual pads and bandages, must be placed in specific trash plastic bags (according to the recommendation stated in section “Trash recommendations” below).
- Wash your underwear, pyjamas, sheets and any clothes that contain sweat, blood or urine separately from the laundry of other members of your household, using a standard washing cycle. You do not need to use bleach and do not need extra rinses.

Trash recommendations
Keep the specific plastic trash bags separated from the other trash; keep the bags away from children and animals.

A member of the hospital staff will tell you how and when to get rid of these trash bags. You might be asked to bring the bag back to your treatment facility, or, after 70 days, the bag may be removed as the other household waste.

Hospitalisation and Emergency Care
If for any reason you require emergency medical assistance or unplanned hospitalisation occurs during the 3 months after your treatment, you should inform the medical providers about the nature, the date and the dose of your radioactive treatment. To facilitate that, carry your discharge letter with you at all times.

Travel
Keep the discharge letter with you whenever you are travelling for at least 3 months after treatment.

The Nuclear medicine doctor will inform you if you need to take any other special precautions after receiving this medicine. Contact your nuclear medicine doctor if you have any questions.

If you have been given more Lutathera than you should
An overdose is unlikely because you will only receive a single dose of Lutathera precisely controlled by the nuclear medicine doctor supervising the administration procedure. However, in the case of an overdose, you will receive the appropriate treatment. Should you have any further question on the use of this medicine, please ask the nuclear medicine doctor who supervises the procedure.

4. Possible side effects
Like all medicines, this medicine can cause side effects, although not everybody gets them.
Lutathera side effects are mainly linked to radioactivity.
The most common side effect seen in patients being treated with Lutathera is the impact on the bone marrow. This can lead to the decrease of the different types of blood cells, most importantly, red blood cells (responsible for transporting the oxygen from the lungs to the different organs), platelets (a special cell which helps the blood to clot), and other blood cells such as white blood cells (helps to fight infection). This happens in many patients and is frequently temporary. However, in rare cases the decrease in blood cells may be long standing and/or permanent.
As a consequence, a decrease in the various blood cell types may put you at risk for bleeding, fatigue, shortness of breath, and infection. If this does occur to you, your doctor may decide to delay or stop the treatment administration.
Some side effects could be serious
If you experience any serious side effects, tell your doctor immediately.

Very common: may affect more than 1 in 10 people
- Spontaneous bleeding or bruising (possible signs of low level of blood platelets) (thrombocytopenia)
- Fever, sore throat or mouth ulcers due to infections (possible signs of low level of white blood cells) (lymphopenia)
- Tiredness, fatigue, pale skin (possible signs of low level of red blood cells) (anaemia)
- Pale skin, weakness, spontaneous bleeding or bruising and frequent infections with signs such as fever, chills, sore throat or mouth ulcers (possible signs of low level of blood cells) (pancytopenia)

Common: may affect up to 1 in every 10 people
- Bone marrow cancer resulting in poorly formed blood cells or ones that do not work properly, with signs and symptoms of anaemia (myelodysplastic syndrome)
- Fever, sore throat or mouth ulcers due to infections (possible signs of low level of white blood cells) (leukopenia and neutropenia)
- Weight gain, tiredness, hair loss, muscle weakness, feeling cold (possible signs of underactive thyroid gland) (secondary hypothyroidism)
- Thirst, low urine output, weight loss, dry flushed skin, irritability (possible signs of dehydration)
- Transient, self-limited loss of consciousness followed by spontaneous recovery (syncope)
- Irregular heart-beat (change in the electrical activity of the heart)
- Dizziness, light-headedness (possible signs of low blood pressure)
- Severely decreased urine output (possible signs of kidney disorders) (renal failure and acute kidney injury)

Uncommon: may affect up to 1 in every 100 people
- Sore throat, runny nose, difficult or painful breathing and fever (possible signs of a respiratory tract infection)
- Cough, difficult or painful breathing, wheezing, pain in chest when breathing, fever (possible symptoms of upper respiratory tract infection) (pneumonia)
- Rash of small fluid-filled blisters, appearing on reddened skin, signs of viral infection that can be potentially severe (herpes zoster)
- Viral infection of the eyes (ophthalmic herpes zoster)
- Staphylococcal infections
- Streptococcal bacteraemia
- Persistent fatigue, frequent or severe infections, easy bleeding, weight loss (possible symptoms of bone marrow cancer) (acute myeloid leukaemia, acute leukaemia and chronic myelomonocytic leukaemia)
- Bone marrow cancer resulting in poorly formed blood cells or ones that do not work properly, with signs and symptoms of anaemia (refractory cytopenia with unilineage dysplasia)
- Nephrogenic anaemia
- Bone pain or fractures, fatigue, increased infections, changes in urination frequency, confusion, thirst, nausea or vomiting, weight loss (possible symptoms of bone marrow failure)
- Bleeding and/or bruising underneath the skin (possible signs of low level of blood platelets) (thrombocytopenic purpura)
- Rash, itching, hives, breathlessness or difficult breathing, wheezing or coughing, light-headedness, dizziness, changes in levels of consciousness, hypotension, with or without mild generalized itching, skin reddening, facial/throat swelling, blue discoloration of the lips, tongue or skin (signs of severe allergic reaction) (hypersensitivity)
- Excessive thirst, high urine output, increased appetite with weight loss, tiredness (signs of high level of sugar in blood) (diabetes mellitus)
• Facial flushing, redness, and a sudden rush of warmth in the face that is sometimes confused with the hot flashes of menopause, diarrhoea, a fast heartbeat, wheezing, a sudden drop in blood pressure (possible signs of carcinoid crisis)
• Nausea, sweating, weakness, dizziness, trembling, headache (sign of low level of sugar in the blood)
• Rapid and shallow breathing, confusion, fatigue, headache, sleepiness, lack of appetite, jaundice, increased heart rate, possible signs of metabolic acidosis that occurs when the body produces excessive quantities of acid or when the kidneys are not removing enough acid from the body (metabolic acidosis)
• Seeing, feeling or hearing things that are not there (hallucination)
• Altered level of consciousness as a result of liver failure (possible signs of hepatic encephalopathy)
• Pressure on the spinal cord nerves which can be caused by a tumour or other lesion (spinal cord compression)
• Irregular heartbeat (atrial fibrillation)
• Sudden and crushing chest pain, tiredness, irregular heart-beat (possible symptoms of heart attack) (myocardial infarction)
• Crushing chest pain (possible symptoms of problem in the heart) (angina pectoris)
• Collapse caused by a heart problem, during which you may become breathless, pale, experience cold sweat and dry mouth (cardiogenic shock)
• Dizziness, fainting on standing up, fall in blood pressure upon standing (orthostatic hypotension)
• Swelling and reddening of a vein (sign of phlebitis)
• Chest pain, cough, hiccups, rapid breathing (signs of fluid collection between the layers of tissue that line the lungs and chest cavity) (pleural effusion)
• Swelling of the abdomen due to accumulation of fluid (ascites)
• Constipation, swollen abdomen, abdominal pain (intestinal obstruction)
• Diarrhoea, abdominal pain, fever (possible signs of inflammation of the colon)
• Vomiting, belching, abdominal pain upper and lower, with or without nausea and vomiting (possible signs of inflammation of the pancreas) (acute pancreatitis)
• Blood vomiting (haematemesis)
• Acute pain and swelling of the abdomen due to accumulation of fluid (haemorrhagic ascites)
• Abdominal pain, general feeling of being unwell (ileus)
• Decreased blood levels of pancreatic enzymes
• Yellow skin and eyes, nausea, loss of appetite, dark urine (signs of liver disorder) (hepatocellular injury)
• Yellow eyes or skin (cholestasis) (signs of liver disorder)
• Liver injury or congestion
• Liver failure
• Acute pre-renal failure
• Death
• Clavicle fracture
Other possible side effects
Other side effects include the following listed below. If these side effects become severe, please tell your doctor, pharmacist or healthcare provider.

**Very common:** may affect more than 1 in 10 people
- Loss of appetite
- Nausea
- Vomiting
- Tiredness (fatigue)

**Common:** may affect up to 1 in every 10 people
- Excessive thirst, high urine output, increase appetite with weight loss (signs of high level of sugar in the blood)
- Sleep disturbance
- Dizziness
- Disturbed sense of taste (dysgeusia)
- Headache
- Feeling of having little energy, fatigue, (lethargy)
- Headache, dizziness (sign of high blood pressure)
- Flushing and hot flushes
- Short of breath, labored breathing (dyspnoea)
- Swelling, feeling of fullness in the abdomen
- Diarrhoea
- Stomach pain
- Constipation
- Upper stomach pain
- Indigestion, pain or an uncomfortable feeling in the upper middle part of your stomach (dyspepsia)
- Stomach pain, nausea (gastritis)
- Yellow skin and eyes, possible symptoms of high amounts of bile pigment (bilirubin) in the blood
- Hair loss (alopecia)
- Pain in muscles, bones or joints
- Muscle spasm
- Blood in urine
- Abnormal results of urine test (presence of serum proteins)
- Skin reaction such as redness or swelling and pain at the site of injection
- Swollen hands, ankles or feet (oedema peripheral)
- Pain in the site of injection
- Chills
- Tiredness, chills, sore throat, joint or muscles aching

**Uncommon:** may affect up to 1 in every 100 people
- Discharge from the eye with itching, redness and swelling (signs of conjunctivitis)
- Painful and frequent urination (possible symptoms of bladder inflammation) (cystitis)
- Flu-like symptoms (Influenza)
- Weight gain, tiredness, hair loss, muscle weakness, feeling cold (signs of underactive thyroid gland) (hypothyroidism)
- Bone and joint pain, excessive urination, abdominal pain, weakness, tiredness (signs of overactive parathyroid gland) (hyperparathyroidism)
- Nausea, shortness of breath, irregular heart-beat, clouding of urine, tiredness and/or joint discomfort associated with abnormal laboratory values - high potassium, uric acid, and phosphorous levels and low calcium levels in the blood (signs of dying tumour cells)
- Excessive emotional distress, troubled (anxiety)
- Disorientation
• A sensation like insects crawling over the skin (formication)
• Sensation of pins and needles (pricking, burning, tingling or numbing sensation) (paraesthesia)
• A distorted sense of smell (parosmia)
• Drowsiness (somnolence)
• Eye disorders
• Dizziness, with spinning sensation (vertigo)
• Rapid or irregular heartbeat or tremor (palpitations)
• Redness and/or facial flushing due to widening of blood vessels (vasodilation)
• Coldness of hands and feet
• Pale skin (pallor)
• Sore throat (oropharyngeal pain)
• Increased sputum
• Choking sensation
• Dry mouth
• Flatulence
• Gastrointestinal pain
• Mouth sores with gum inflammation (stomatitis)
• Passage of fresh blood through the anus usually in or with stool (haematochezia)
• Abdominal discomfort
• Bloody stools (rectal haemorrhage)
• Black stools (melaena)
• Lower abdominal pain
• Rash
• Dry skin
• Swelling face
• Excessive sweating (hyperhidrosis)
• Generalized itching (pruritus generalised)
• Abnormal results of urine test (presence of leukocytes)
• Involuntary leakage of urine (urinary incontinence)
• Test result that indicates kidney disorders (glomerular filtration rate decreased)
• Kidney disorder
• Renal impairment
• Injection site mass
• Tiredness, chest discomfort, light headedness pain, palpitations (possible signs of heart disorder)
• Chest pain
• Fever
• Generally feeling unwell (malaise)
• Pain
• Feeling abnormal
• Loss of weight
• Physical disability
During Lutathera treatment, you may also have side effects of abnormal blood test results, which can give your doctor information on the functioning of some parts of your body

**Common:** may affect up to 1 in every 10 people
- High level of the following enzymes:
  - Gamma glutamyl transferase, alanine amino transferase, aspartate amino transferase, blood alkaline phosphate
  - High level of blood creatinine
  - Low levels of magnesium and sodium in the blood

**Uncommon:** may affect up to 1 in every 100 people
- High level of the following enzymes:
  - High level of creatine phosphokinase in the blood that may indicate muscle damage, such as of the heart
  - High level of lactate dehydrogenase in the blood that gives information about the health of certain organs
  - Low levels of potassium, phosphate, calcium and albumin in the blood
  - High levels of sodium, calcium, urea, glycosylated hemoglobin, catecholamines and c-reactive protein in the blood
  - Haematocrit decreased
  - Presence of protein in urine

During Lutathera treatment, you may also have surgical/medical procedures

**Common**
- Blood transfusion

**Uncommon**
- To drain fluid from the peritoneal cavity, the space between the abdominal wall and organs (abdominal cavity drainage)
- To filter your blood to rid your body of harmful wastes, extra salt, and water (dialysis)
- To place a stent
- To drain abscess
- For gastrointestinal tube insertion
- To harvest (collect) stem cells from your bone marrow (bone marrow harvest)
- To remove polyps from the inside of the colon, also called the large intestine (polypectomy)

**Reporting of side effects**
If you get any side effects, talk to your nuclear medicine doctor. This includes any possible side effects not listed in this leaflet. You can also report side effects directly via the national reporting system listed in Appendix V. By reporting side effects you can help provide more information on the safety of this medicine.

5. **How Lutathera is stored**

You will not have to store this medicine. This medicine is stored under the responsibility of the specialist in appropriate premises. Storage of radiopharmaceuticals will be in accordance with national regulation on radioactive materials.

The following information is intended for the specialist only.

Keep this medicine out of the sight and reach of children.

Lutathera must not be used after the expiry date which is stated on the label after EXP.

Store below 25 ºC.

Store in the original package to protect from radiation.
6. Contents of the pack and other information

What Lutathera contains
- The active substance is lutetium (\(^{177}\text{Lu}\)) oxodotreotide. One mL of solution for infusion contains 370 MBq lutetium (\(^{177}\text{Lu}\)) oxodotreotide at the date and time of calibration.
- The other ingredients are: acetic acid, sodium acetate, gentisic acid, ascorbic acid, diethylene triamine pentaacetic acid (DTPA), sodium chloride 9 mg/mL (0.9%) solution for injection, sodium hydroxide, water for injections (see section 2 “Lutathera contains sodium”).

What Lutathera looks like and contents of the pack
Lutathera is a clear and colourless solution for infusion, supplied in a colourless glass vial closed with a rubber stopper and sealed with an aluminium capsule. Each vial contains a volume varying from 20.5 to 25.0 mL of solution corresponding to an activity of 7,400 MBq at date and time of infusion. The vial is enclosed within a plastic sealed, lead shielded container.
