International Cooperation on Harmonisation of Technical Requirements
for Registration of Veterinary Medicinal Products

VICH GL13 (ANTHELMINTICS OVINES)
May 2022
Revision at Step 9
For consultation at Step 4

EFFICACY OF ANTHELMINTICS: SPECIFIC RECOMMENDATIONS FOR OVINES (REVISION 1)

Revision at Step 9
Recommended for Consultation at Step 4 of the VICH Process
in May 2022
by the VICH Steering Committee

This Guideline has been developed by the appropriate VICH Expert Working Group will be subject to consultation by the parties, in accordance with the VICH Process. At Step 7 of the Process the final draft is recommended for adoption to the regulatory bodies of the European Union, Japan and USA.

Secretariat: c/o HealthforAnimals, 168 Av de Tervueren, B-1150 Brussels (Belgium) - Tel. +32 2 543 75 72

EFFICACY OF ANTHELMINTICS: SPECIFIC RECOMMENDATIONS FOR OVINES

INTRODUCTION

These guidelines for ovines were developed by the Working Group established by the Veterinary International Cooperation on Harmonization (VICH), Anthelmintic Guidelines and subsequently revised in 2022. They should be read in conjunction with the VICH Efficacy of Anthelmintics: General Requirements (VICH GL7) which should be referred to for discussion of broad aspects for providing pivotal data to demonstrate product anthelmintic effectiveness. The present document is structured similarly to VICH GL7 with the aim of simplicity for readers comparing both documents.

The aim of the guidelines for ovines is (1) to be more specific for certain specific issues for ovines not discussed in VICH GL7; (2) to highlight differences with VICH GL7 on efficacy data requirements and (3) to give explanations for disparities with VICH GL7.

It is also important to note that technical procedures to be followed in the studies are not the aim of this guideline. We recommend to the sponsors to refer to the pertinent procedures described in detail in other published documents e.g. WAAVP Second Edition of Guidelines for Evaluating the Efficacy of Anthelmintics in Ruminants (Bovine, Ovine, Caprine) Veterinary Parasitology 58: 181-213, 1995, and updated versions as they are published.

A. General Elements

1 - The Evaluation of Effectiveness Data

Only controlled tests based on parasite counts of adults/larvae are acceptable both for the dose determination and dose confirmation studies, since critical tests generally are not considered to be reliable for ruminants. Egg counts/larval identification is the preferred method to evaluate the effectiveness in field studies. Long-acting or sustained-release products should be subject to the same evaluation procedures as other therapeutic anthelmintics. Adequate parasite infection should be defined in the protocol according to regional prevalence or historical data and/or statistical analysis.

2 - Use of Natural or Induced Infections

Dose determination studies generally should be conducted using induced infections with either laboratory strains or recent field isolates. If no infection model exists for a parasite species (*Protostrongylidae*, cestodes, *Dicrocoelium* spp.), the use of natural infections instead of induced infections is justified.

Dose confirmation studies should be conducted using naturally infected animals, however, induced infections or superimposed induced infections can also be used. This procedure will allow a wide range of parasites to be present. For claims against 4th stage larvae, induced infections must be used. For claims against hypobiotic larvae, only natural infections can be considered. Sponsors should aim for a maximum period of accumulation of hypobiotic larvae for the particular parasite species being targeted in trial animals. This will be area or regionally dependent. Specific details on area or regional situations should be obtained from experts on a case by case basis, if needed. In all cases, animals need to be housed (to preclude reinfection) for a minimum of 2 weeks before treatment.

Persistent efficacy studies should be conducted using induced infections with recent field isolates. The history of the parasites used in the induced infection studies should be included

111 in the final report.

112
113 **3 - Number of Infective Parasitic Forms Recommended for Induced Infections**

114
115 The number to be used is approximate and will depend on the isolate that is used. The final
116 number of larvae used in the infection should be included in the final report. Table 1 shows the
117 range of numbers recommended for parasites with existing infection models.

118
119 **Table 1 - Number of Infective Stages Used to Produce Adequate Infections in**
120 **Sheep for Anthelmintic Evaluation**
121

Parasite Anatomical Location <i>Genus Species</i>	Range of eggs/larvae
Abomasum	
<i>Haemonchus contortus</i>	400 – 4,000
<i>Teladorsagia circumcincta</i>	6,000 – 10,000
<i>Trichostrongylus axei</i>	3,000 – 6,000
Intestines	
<i>Cooperia curticei</i>	3,000 – 6,000
<i>T. colubriformis</i> & <i>T. vitrinus</i>	3,000 – 6,000
<i>Nematodirus</i> spp.	3,000 – 6,000
<i>Oesophagostomum</i> spp.	500 – 1,000
<i>Chabertia ovina</i>	800 – 1,000
<i>Bunostomum trigonocephalum</i>	500 – 1,000
<i>Strongyloides papillosus</i>	80,000
<i>Gaigeria pachyscelis</i>	400
<i>Trichuris</i> spp.	1,000
Lungs	
<i>Dictyocaulus filaria</i>	1,000 – 2,000
Liver	
<i>Fasciola hepatica</i> (metacercaria)	
	100 - 200 (chronic)
	1,000 – 1,500 (acute)

122
123 **4 - Recommendations for the Calculation of Effectiveness**

124
125 **4.1 Criteria to Grant a Claim**

126 To be granted a claim the following pivotal data should be included:

- 127
128
129
130 a) Two dose confirmation studies conducted with a minimum of six adequately infected non-
131 medicated animals (control group) in each study. The infection of the animals in the study
132 will be deemed adequate based on historical, parasitological and/or statistical criteria.
133
134 b) The differences in parasite counts between treated and control animals should be
135 statistically significant ($p \leq 0.05$).
136
137 c) Percent efficacy should be 90% or higher and calculated and interpreted using the
138 procedures described in Section 4.2 of VICH GL7.

139
140 **4.2 Number of Animals (Dose Determination, Dose Confirmation and Persistency trials)**

141
142 The minimum number of animals required per experimental group is a critical point. Although
143 the number of animals will depend on the possibility to process the data statistically according
144 to adequate statistical analysis, it has been recommended, to achieve harmonization, that the
145 inclusion of at least 6 animals in each experimental group is a minimum.

146
147 In cases where there are several studies none of which have 6 adequately infected animals

148 in the control group (for example, important rare parasites), the results obtained could be
149 pooled to accumulate 12 animals in the studies; and statistical significance calculated. If the
150 difference is significant ($p < 0.05$), effectiveness may be calculated and if the infection is
151 deemed adequate, the claim may be granted. Sampling techniques and estimation of worm
152 burden should be similar among laboratories involved in the studies to allow adequate and
153 meaningful extrapolation of the results to the population.

154 155 **4.3 Adequacy of Infection**

156
157 The minimum adequate number of helminths in individual control animals should be defined
158 in the protocol. However, final conclusions regarding adequacy of infection will be made as
159 part of the final report based on statistical analysis, historical data, literature review, or expert
160 testimony. The range of ovine helminths (adults) that has been considered adequate to grant
161 a claim will vary according to the species. Generally, a minimum of 100 nematodes in
162 individual control animals is considered an adequate infection. Lower individual counts are
163 to be expected with *Bunostomum* spp., *Oesophagostomum* spp., *Trichuris* spp., *Gaigeria*
164 *pachyscelis* and *Dictyocaulus filaria*. For *Fasciola* spp. minimum counts of 20 adults are
165 considered adequate.

166 167 **4.4 Label Claims**

168
169 For adult claims as a general rule, the treatment should not be administered earlier than 21
170 to 25 days after infection; optimum for most species is 28 to 32 days. Major exceptions are
171 *Oesophagostomum* spp. (28 to 41 days), *Bunostomum* spp. (52 to 56 days), *Strongyloides*
172 *papillosus* (14 to 16 days) and *Fasciola* spp. (8 to 12 weeks).

173
174 For L4 claims, treatments should be given on the following days after infection: 3 to 4 days for
175 *Strongyloides papillosus*, 5 to 6 days for *Haemonchus* spp., *Trichostrongylus* spp. and
176 *Cooperia* spp., 7 days for *T.(O.) circumcincta*, 8 to 10 days for *Nematodirus* spp., and *D.*
177 *filaria* and 15 to 17 days for *Oesophagostomum* spp. The term immature on the labelling is
178 not acceptable for these claims.

179
180 For early immature *Fasciola* spp., treatments should be given 1 to 4 weeks after infection
181 and for late immatures at 6 to 8 weeks.

182 183 **5 - Treatment Procedures**

184
185 The method of administration (oral, parenteral, topical, slow-release etc.), formulation and
186 extent of activity of a product will influence the protocol design. It is advisable to consider the
187 weather and animal relationship with regard to effectiveness of topical formulations. Slow-
188 release products should be tested over the entire proposed effective time unless additional
189 information suggests that this is unnecessary, e.g. blood levels demonstrate steady state at
190 all points of the proposed therapeutic period.

191
192 When the drug is to be administered in the water or in a medicated feed, it should be done as
193 much as possible following the labelling recommendations. Palatability studies may be required
194 for medicated feed. Samples of medicated water or feed should be collected to confirm drug
195 concentration. The amount of medicated product provided to each animal should be recorded
196 to ensure that the treatment satisfies the label recommendations. For products used topically,
197 the impact of weather (e.g. rainfall, UV light), and coat length should be included in the
198 evaluation of the effectiveness of the product.

199 200 **6 - Animal Selection, Allocation and Handling**

201
202 Test animals should be clinically healthy and representative of the age, sex, and class for which
203 the claim of the test anthelmintic is to be made. In general, the animals should be ruminating,
204 and older than 3 months of age. Randomization to treatment group should be performed using

205 an adequate method that should be described in the protocol and final report. Blocking should
206 only be employed if it is expected to reduce residual error in the study. If blocking is used,
207 blocks should be included as a random effect in the statistical model. Nevertheless, blocking
208 is not always the most appropriate method for reducing residual error. Alternative methods
209 may therefore be considered e.g. a suitably selected covariate.
210

211 For induced infections, the use of helminth naive animals is recommended. Animals not
212 raised in a helminth-free environment should be treated with an approved anthelmintic,
213 chemically not related to the test drug, to remove pre-existing infections followed by faecal
214 examination to determine that the animals are helminth free.
215

216 Animal housing, feeding and care should follow strict requirements of welfare, including
217 vaccination according to local practices. This information should be provided in the final report.
218 A minimum 7-day acclimatisation period is recommended. Housing and feed/water should be
219 adequate according to the geographical location. Animals should be monitored daily to
220 determine adverse reactions.
221

222 **B. Specific Evaluation Studies**

223
224

225 **1 - Dose Determination Studies**

226
227 No species specific recommendations.
228

229 **2 - Dose Confirmation Studies**

230
231 Confirmation studies are needed to support each claim: adult, larvae and when applicable
232 hypobiotic larvae.
233

234 **3 - Field Efficacy Studies**

235
236 The field studies should be replicated in different geographic locations and in animal/production
237 class(es) that represent the conditions of use for the indication being pursued. The protocol
238 should state the number of experimental units per treatment group (sample size), describe
239 allocation (proportion) to treatment groups, and include a brief description of how the sample
240 size was determined. The protocol should also describe procedures for random selection of
241 animals (number and percentage) to be sampled (if faecal samples will not be collected from all
242 available animals in the study), as appropriate, and the methods to be used for both faecal
243 collection and examination. Regardless of whether one or multiple parasites are being evaluated
244 within a study, an appropriate sample size calculation or justification is necessary prior to study
245 conduct.
246

247 Effectiveness against adult nematodes can be assessed by the reduction of faecal egg counts
248 and should be performed using samples from the same animal before and after treatment in both
249 study groups (control and treated). Post-treatment counts are generally made 10-14 days after
250 treatment, but the timing of post-treatment counts will depend on the parasite species and class
251 of anthelmintic evaluated. For example, due to the known effects of macrocyclic lactones on
252 nematode egg suppression, post-treatment counts should be delayed until at least 14 days or
253 longer. Efficacy should be calculated using post-treatment faecal egg counts from the treated
254 and control (typically placebo or untreated control) groups. Additionally, a calculation of efficacy
255 using pre- and post-treatment faecal egg counts may provide further information on field
256 effectiveness. Furthermore, additional endpoints for evaluating field effectiveness should be
257 considered as they are developed and generally accepted by experts in veterinary parasitology.
258

259 See also Sections 4.1 and 4.2 of VICH GL7.
260

261 **4 - Persistent Efficacy Studies**

262
263 Two basic study designs have been used to pursue persistent efficacy claims: one using a
264 single challenge, another using multiple daily challenges following treatment. For both
265 procedures, no standardised protocols have been developed. When conducting studies,
266 protocols details should include among other things: determination of larval viability throughout
267 the study, rationale for larval challenge and justification of slaughter time. Parasite naive sheep
268 are recommended in these studies. A study design is recommended using multiple daily
269 challenges, as this most closely mimics what occurs in nature.
270

271 A minimum requirement for a persistent efficacy claim (for each duration and helminth claim)
272 should include 2 trials (with worm counts) each with a non-treated and one or more treated
273 groups. At least 6 animals in the control group shall be adequately infected. Persistent efficacy
274 claims will only be granted on a species-by-species basis.
275

276 In the protocol using multiple daily challenges, different groups of animals are treated and
277 exposed to a daily natural or induced challenge for 7, 14, 21 or more days after the treatment,
278 then at approximately 3 weeks after the last challenge (or earlier) the animals are examined for
279 parasite burden. The challenge interval and schedule may vary for longer acting products, and
280 should take into consideration the pharmacological properties of the product.
281

282 Persistent efficacy claims should be supported by a minimum 90% efficacy at each time
283 point and calculated and interpreted using the procedures described in Sections 4.1 and
284 4.2 of VICH GL7. Persistent efficacy claims should be granted for the longest period
285 between treatment and the last challenge where effectiveness criteria are met and all
286 preceding time points tested meet the criteria as well.
